(54) **Small hole electric discharge machine drill provided with depth-specific processing means and method of depth-specific processing with small hole electric discharge machine drill**

(57) Disclosed is a method of depth-specific processing with a small hole electric discharge machine drill. Firstly, a specified processing depth A and tolerance a are registered with a program. Secondary, an origin of initiation of drilling is set on a surface of a workpiece by contacting a tip of an electrode D with the surface of the workpiece at a check point. Thirdly, the electrode is moved to a processing position to process until the specified processing depth. Fourthly, the electrode is moved to a position above the check point. Fifthly, the electrode is moved downward until the electrode contacts the surface of the workpiece, a Z-axis coordinate upon contact is defined as C. And finally, a condition judgment is made concerning C which is found in the fifth step, as to whether or not $|C| \leq \alpha$ is satisfied. If the condition is satisfied, then processing is completed.

FIG. 1

Description

BACKGROUND OF THE INVENTION

Field of the Invention

[0001] The present invention relates to a small hole electric discharge machine drill provided with depth-specific processing means and with a turntable which is tiltable in water, and to a method of depth-specific processing with the small hole electric discharge machine drill.

Description of the Related Art

[0002] To date, there have been no small hole electric discharge machine drills (hereinafter referred to as "small hole EDM drills") provided with turntables which are usable in water as well as tiltable. Therefore, small hole processing with various inclinations with respect to a worked surface has been performed on a workpiece on a worktable set out in the air.

[0003] In the meantime, there are the following two methods of specifying depth of a processed small hole in a small hole processing method using a conventional small hole EDM drill.

1. A method that an attrition degree of an electrode to be used is measured in advance by test processing or the like, and then a depth-specific value (a Z-axis travel instruction value) is determined while reflecting the measured value.

2. A method that an attrition degree of an electrode to be used is measured in advance by test processing or the like in order to enhance precision of a depth of a processed hole, and processing takes place in a processing repetition frequency determined in advance in the event of processing according to a depth-specific value (a Z-axis travel instruction value) which reflects the measured value.

[0004] Now, description will be made a little more concretely regarding the foregoing second method.

(1) A tip of an electrode is aligned in a position on a surface of a workpiece and the position is set as an origin ($Z=0$) to initiate drilling, and then the workpiece is processed until a specified depth in accordance with the depth-specific value (the Z-axis travel instruction value) reflecting the above-described measured value.

(2) After the step (1) is finished, the tip of the electrode is aligned once again in the position on the surface of the workpiece and the position is set again as an initial point ($Z=0$) of processing (while canceling an attrition amount of the electrode), and then the workpiece is processed until the specified depth as set in the step (1).

(3) The step (2) is repeatedly performed in a specified frequency, and the process is completed.

SUMMARY OF THE INVENTION

[0005] However, conventional small hole processing by use of a bar pipe electrode has a problem that a process fluid from the inside of the pipe is not sufficiently supplied to a processed portion on an extracting edge of a processed hole thus causing aerial discharge, whereby the electric discharge becomes unstable and processing time is increased. There is also a problem that heat accruing from the electric discharge causes discoloration or deterioration of a workpiece, and incurs burrs on an entrance portion of the processed hole. Moreover, the above-described method 1 of the related art also has a problem that the attrition degree of the electrode varies depending on conditions of electric discharge processing (such as electric processing conditions, materials of electrodes and workpieces, and depths of processed holes, for example), therefore, it is difficult to find an accurate depth-specific value. In addition, measuring an attrition degree of an electrode requires a lot of time.

[0006] Meanwhile, regarding the method 2 of the related art, there is a problem that the frequency needs to be increased for enhancing precision of a depth of a processed hole, whereby processing time per hole becomes extremely long when high precision is expected.

[0007] The present invention has been made to resolve the foregoing problems. A first object of the present invention is to provide a small hole electric discharge machine drill provided with depth-specific processing means and with a tiltable turntable which is usable in water. In addition, a second object of the present invention is to provide a method of depth-specific processing upon small hole electric discharge processing with a small hole electric discharge machine drill, which does not require measurement of an attrition degree of an electrode prior to processing, and which is capable of processing a hole with a depth in a range of desired precision without specifying a repetition frequency.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008]

Fig. 1 is a front view showing a small hole electric discharge machine drill according to one embodiment of the present invention, which is provided with depth-specific processing means capable of depth-specific processing.

Fig. 2 is a right side view of Fig. 1.

Fig. 3 is a partially enlarged view of a portion corresponding to a turntable unit 17 in Fig. 2.

Fig. 4 is a cross-sectional view taken along a line IV-IV in Fig. 3.

Fig. 5 is a block diagram describing a constitution of a CNC control unit provided with the depth-specific processing means according to the present invention.

Fig. 6 is a view for describing a relation between a processed hole and tolerance in the case of processing a small hole with a depth A.

Fig. 7 is a view for describing a process situation by the method of depth-specific processing according to the present invention upon small hole electric discharge processing.

Fig. 8 is a flowchart for describing processing steps of the method of depth-specific processing according to the present invention upon small hole electric discharge processing.

DESCRIPTION OF THE PREFERRED EMBODIMENT

[0009] Now, an embodiment of the present invention will be described with reference to the accompanying drawings.

[0010] Fig. 1 to Fig. 4 collectively show one embodiment of the present invention, which is a small hole electric discharge machine (EDM) drill 10 of six-axis control (X, Y, W, Z, A and B) provided with a computer numerical control (CNC) control unit.

[0011] On a pedestal 4 of the small hole EDM drill 10 as collectively illustrated in the drawings, provided is a Y-axis table 6 capable of traveling and aligning in a Y-axis direction by unillustrated driving means and by a Y-axis driving motor M_Y .

[0012] A tray 7 is provided as integrally fixed to the Y-axis table 6. An insulative stone surface plate 9 is provided on the tray 7, and an L-shaped bracket member 11 is integrally provided on the stone surface plate 9.

[0013] A work tank 15 for containing a working fluid 13 such as low-conductive deionized water is fitted on the above-mentioned bracket member 11. A tiltable turntable unit 17 for fixing a workpiece W thereto is provided inside the work tank 15.

[0014] Now, description will be made further in detail regarding the above-mentioned turntable unit 17 with reference to Fig. 3 and Fig. 4.

[0015] The turntable unit 17 includes an A axis with the center of rotation on a shaft center parallel to a Z axis (in the longitudinal direction in Fig. 1 or Fig. 3), and a B axis (a tilting axis) with the center of rotation on a shaft center orthogonal to the A axis (parallel to a Y axis and orthogonal to an X axis).

[0016] A B-axis rotating shaft 19 as a driving portion of the above-mentioned B axis is rotatably supported by a B-axis fitting portion 11b via a bearing 21. Here, the B-axis fitting member 11b extends upward along a right side wall surface (on the right side in Fig. 2 or Fig. 3) of the work tank 15 from a horizontal bottom portion 11a of the L-shaped bracket member 11 on the stone surface plate 9. The B-axis rotating shaft 19 is provided so as to penetrate the right side wall surface of the work tank

15 and extend to almost a central portion inside the work tank 15.

[0017] An outer ring and an inner ring of the bearing 21 are fixed to the B-axis fitting portion 11b of the L-shaped bracket member 11 with an annular bearing holder 22 and an annular nut member 24.

[0018] On a shaft center portion of the B-axis rotating shaft 19, provided is a blind hole 23 which has an opening on a right end thereof and extends horizontally towards the vicinity of a left end thereof along the shaft center of the B-axis rotating shaft 19. Moreover, a turntable 27 is fitted to an upper portion on the left end of the B-axis rotating shaft 19 via a speed reducer 25 with a large axle ratio (about 1/100) such as Harmonic Drive™.

[0019] A bottom housing portion 26a of the above-mentioned speed reducer 25 is fixed to the B-axis rotating shaft 19 in a state of protruding inward the blind hole 23. An input shaft 29 for A-axis driving, which is rotatably supported by this bottom housing portion 26a, protrudes out of the bottom housing portion 26a. A timing pulley 31 is fitted to this input shaft 29.

[0020] Meanwhile, inside an upper housing portion 26b of the speed reducer 25, an output shaft 33 for A-axis driving is provided rotatably via a bearing 35. A bottom face of the above-mentioned turntable 27 is fixed integrally to an upper end of this output shaft with fastening parts such as screws (illustration omitted).

[0021] Moreover, an A-axis drive motor M_A is fitted via a bracket 37. Here, the bracket 37 is fitted so as to stride across the opening of the blind hole 23 of the B-axis rotating shaft 19. A timing belt 41 is girded between a timing pulley 39 provided on an output shaft of this A-axis drive motor M_A and the timing pulley 31 provided on the input shaft 29 of the speed reducer 25.

[0022] In addition, a B-axis drive motor M_B for driving the B-axis rotating shaft 19 is provided inside an air chamber 43 which is fitted to the L-shaped bracket member 11. This air chamber 43 is provided so as to shut out the outside air from the opening of the blind hole 23 of the B-axis rotating shaft 19 and to surround and enclose the A-axis drive motor M_A and the B-axis drive motor M_B .

[0023] Moreover, a timing pulley 45 is provided on an output shaft of the B-axis drive motor M_B , and a timing belt 49 is girded between a timing pulley 47 provided on an outside diametrical portion at a right end of the B-axis rotating shaft 19 and the timing pulley 45.

[0024] A space between the inside of the housing of the speed reducer 25 and the work tank 15 is sealed with a seal 51 to avoid infiltration of the working fluid 13 into the speed reducer 25. Moreover, an appropriate seal such as an O ring is also provided at an engaging portion of the bottom housing portion 26a and the blind hole 23 of the B-axis rotating shaft 19 to avoid infiltration of the working fluid 13 into the blind hole 23.

[0025] Moreover, a seal 53, a seal holder 55 and the like are also provided at an engaging portion where the

B-axis rotating shaft 19 penetrates the wall surface of the work tank 15 in order to prevent leakage of the working fluid 13 to the outside of the tank. Furthermore, the air chamber 43 constitutes an airtight state by sealing off from the outside air, and simultaneously depressurizes the air from a pneumatic source 57 to about 1.1 atm. with a pressure reducing valve 59 for supplying the depressurized air into the air chamber 43 at any time, whereby the working fluid 13 is inhibited from leaking in the blind hole 23 and the air chamber 43.

[0026] On a back surface of the turntable 27, provided is an annular electroconductive ring 61 which is electrically conductive to the turntable 27. An electroconductive brush 63 which always contacts with this electroconductive ring 61 is supported by an electroconductive brush supporting member 65 provided on the B-axis rotating shaft 19.

[0027] Note that the electroconductive brush 63 and an electrode D are connected with an electric discharge power source (illustration omitted).

[0028] In the above-described constitution, it is possible to rotate the turntable 27 around the A axis by an appropriate angle if the A-axis drive motor M_A is rotated appropriately under control of a control unit 12 to be described later. Similarly, it is possible to tilt the turntable 27 clockwise or counterclockwise if the B-axis drive motor M_B is rotated normally or in reverse as appropriate. Furthermore, it is possible to align the turntable 27 in an arbitrary position in the Y-axis direction by appropriately rotating the Y-axis drive motor M_Y .

[0029] Now, while referring to Fig. 1 and Fig. 2, provided on the pedestal 4 at the back of the work tank 15 (at the right side in Fig. 1) is a gate frame 67, which is composed of right and left braces 67a and 67b and a beam member 67c laid over the right and left braces 67a and 67b.

[0030] A guide rail (illustration omitted) protected by bellows 69 is provided on the beam member 67c of the gate frame 67, and an X-axis carriage 71 is provided movably on this guide rail. In addition, provided on this X-axis carriage 71 is a Z-axis carriage 73, which can travel and be aligned to an arbitrary position along the Z axis (a processing axis) by a Z-axis drive motor M_Z . Note that the X-axis carriage 71 can be aligned to an arbitrary position along the X axis by an X-axis drive motor M_X . Moreover, provided on the Z-axis carriage 73 is a W-axis drive motor M_W , which moves the Z-axis carriage 73 to an appropriate height with respect to the X-axis carriage 71.

[0031] The hollow or solid bar electrode D for small hole processing is rotatably supported by the Z-axis carriage 73. In addition, provided is a motor (illustration omitted) for rotating the bar electrode D around the A axis. Moreover, working fluid supplying means (illustration omitted) for supplying the working fluid (such as deionized water) is provided when the bar electrode D is a hollow electrode (that is, a pipe electrode).

[0032] Fluid level controller 77 is provided on the work

tank 15 for controlling a fluid level of the working fluid in accordance with a position of a surface of a workpiece. For example, the Fluid level controller 77 has a constitution as follows.

[0033] As shown in Fig. 1, a notch 79 is provided on a sidewall of the work tank 15 from an upper portion thereof downward to a depth of H. Moreover, a gate 81 is provided as capable of ascending and descending along the notch 79 by appropriate guiding means (illustration omitted). A nut member 83 is provided integrally on the gate 81. A feed screw 85, which is rotated by a gate drive motor M_L fitted to the work tank 15, is screwed into the nut member 83.

[0034] Note that the depth H of the above-mentioned notch 79 is designed as slightly lower than the position of the surface of the turntable 27 when the turntable 27 is in a horizontal position (when a B-axis rotation angle is at 0°).

[0035] The fluid level inside the work tank 15 can be arbitrarily set by moving the gate 81 of the above-described Fluid level controller 77 up and down by driving the gate drive motor M_L .

[0036] In other words, the working fluid 13 is arranged to be supplied to the work tank 15 at any time from a working fluid supplying unit (illustration omitted), and the working fluid 13 is arranged to overflow at any time from this notch 79 to the tray 7. A drain outlet 87 is provided on the tray 7, and the working fluid 13 is arranged to return to a tank of the working fluid supplying unit (illustration omitted) through the drain outlet 87.

[0037] Instead, the above-described Fluid level controller 77 may include a valve at a bottom portion of the work tank 15 and fluid level detector controlling drainage of the working fluid 13. Similar fluid level control is thereby feasible.

[0038] On the brace 67b of the gate frame 67, provided is a CNC control unit 12 which can control the six control axes (X, Y, W, Z, A and B) among others. This CNC control unit 12 can perform three-dimensional (X, Y and Z) alignment of the bar electrode D with respect to a workpiece W by controlling the X-axis drive motor M_X , the Y-axis drive motor M_Y and the Z-axis drive motor M_Z .

[0039] As shown in Fig. 5, data inputting means 16 such as a keyboard, displaying means 18 such as a liquid crystal display device, a process program memory 20 and the like are connected to a data bus DB of a central processing unit 14 provided on the above-mentioned CNC control unit 12.

[0040] In addition, origin setting means 22 for setting an origin ($Z=0$) at initiation of drilling by contacting a tip of the bar electrode D onto a checking point P, process error detecting means 24 for finding a Z-axis coordinate ($Z=C$) when the tip of the bar electrode D contacts the surface of the workpiece and subsequently detecting an process error E ($E=|A-B| = |C|$) from the Z-axis coordinate C, and process error judging means 26 for judging as to whether or not the detected process error E re-

mains within a range of tolerance α ($|C| \leq \alpha$) are connected to the data bus DB. Moreover, the origin setting means 22, the process error detecting means 24 and the process error judging means 26 collectively constitute depth-specific processing means 28.

[0041] In the above-described constitution, when small hole processing takes place, the workpiece W is fitted to the turntable 27 in the state that the working fluid 13 is drained out of the work tank 15. Thereafter, the working fluid 13 (such as deionized water) is injected until the surface of the workpiece W is soaked in the working fluid 13.

[0042] Subsequently, a distance between the surface of the workpiece W and the tip of the bar electrode D is appropriately set by the W-axis drive motor M_w , as well as the X-axis drive motor M_x and the Y-axis drive motor M_y are appropriately driven to align the bar electrode D to desired X-Y coordinates on the workpiece W. Eventually, electric discharge processing can be performed while controlling travel of the bar electrode D along the Z axis by the Z-axis drive motor M_z .

[0043] Moreover, by rotating the A axis and the B axis of the turntable 27 by appropriate angles in the above-described small hole processing, it is possible to perform electric discharge processing on the workpiece W with respect to all surfaces except a bottom surface thereof without re-fitting the workpiece W to the turntable 27.

[0044] In addition, the fluid level of the working fluid 13 inside the work tank 15 can be controlled automatically by the Fluid level controller 77 so as to position slightly higher than the level of the surface of the workpiece W at any time.

[0045] Next, description will be made regarding a method of depth-specific processing with the above-mentioned small hole EDM drill with reference to the accompanying drawings.

[0046] Fig. 6 is a view showing a state of processing a small hole 1 of a depth A from the surface of the workpiece W. The depth of the processed hole 1 should be sufficiently in a range $A \pm \alpha$. Here, α denotes tolerance with respect to the depth A of the processed hole.

[0047] Fig. 7 is an explanatory view for a process situation by the method of depth-specific processing according to the present invention upon small hole electric discharge processing. Fig. 8 is a flowchart for describing processing steps of the method of depth-specific processing according to the present invention upon small hole electric discharge processing.

[0048] In the following, the processing steps of the method of small hole processing according to the present invention will be described with reference to Fig. 7 and Fig. 8.

[0049] In the case of processing the small hole 1 with the depth in the range $A \pm \alpha$, for example, a process program is registered with the process program memory 20 provided on the CNC control unit 12 of the six-axis control (X, Y, W, Z, A and B) small hole EDM drill 10

shown in Fig. 1 (Step S1). Here, the process program includes position coordinates (X, Y) of the processed hole, the depth (A) of the processed hole, the tolerance (α) with respect to the depth (A), a diameter of the processed hole, electric processing conditions and the like.

[0050] Subsequently, the electrode D is moved toward a position above the origin check point P which is set up in an arbitrary position on the surface of the workpiece W in order to confirm a Z-axis origin of the bar electrode D, and then the electrode D is moved toward a negative direction of the Z axis, that is, downward to the surface of the workpiece W, whereby the Z-axis coordinate in the event that the tip of the electrode D contacted the surface of the workpiece W is set to $Z=0$ (or reset to $Z=0$) (Step S2).

[0051] A publicly-known detecting method is used for contact detection of the electrode D with the surface of the workpiece W. For example, one of publicly-known detecting methods is to detect electric conduction between the electrode D and the workpiece W. In addition, the electrode D is designed to stop traveling along the Z axis immediately upon contact detection.

[0052] Subsequently, the electrode D is lifted up and moved to the position (X, Y) to perform processing, and then the electrode D is moved downward along the Z axis until the Z-axis coordinate thereof reaches $Z=-A$, thus drilling the small hole 1 of a specified processing depth of A (Step S3).

[0053] In the above-mentioned process until the specified processing depth of A, the tip of the electrode D is consumed during electric discharge processing and thereby shortened. Accordingly, if a depth of the small hole actually processed is B and a consumed length of the electrode D is C, then $B=A-C+\delta$. Here, δ denotes an electric discharge gap between the tip of the electrode and the bottom of the processed hole, which is a very small value in a range from about 0.005 mm to 0.01 mm. Therefore, if precision of the depth specification of the processed hole can ignore δ , then the depth B of the small hole actually processed can be calculated as $B=A-C$ assuming that $\delta=0$. In the following, description will be made based on the assumption that $\delta=0$.

[0054] Subsequently, the tip of the electrode D is lifted up from the Z-axis coordinate $Z=0$ and moved to a position above the check point P (Step S4). At the check point P, the tip of the electrode D is moved down to contact the surface of the workpiece W, and then a Z-axis coordinate where the tip of the electrode D contacts the workpiece W is determined as $Z=C$ (Step S5).

[0055] The above-described Z-axis coordinate $Z=C$ coincides with the consumed length of the electrode D upon processing until the specified processing depth A in Step S3. In other words, the consumed length C of the electrode D in Step S3 is thereby found. Therefore, if a process error is E, then:

$$E=|A-B|=|C| \quad (1)$$

[0056] Subsequently, condition judgment (Step S6) takes place as to whether or not the error $E (=|CI|)$ of the processed hole in Step S3 remains within the tolerance α ; that is:

$$|CI| \leq \alpha \quad (2)$$

If such a condition is not satisfied, then a routine from Step S2 to Step S6 will be iterated until the condition is satisfied in Step S6.

[0057] When the condition is satisfied in Step S6, small hole processing in this processing position is completed. In this event, the depth B of the small hole actually processed remains in a range $A+\alpha \geq B \geq A-\alpha$, as derived from the formulas (1) and (2).

Claims

1. A method of depth-specific processing of a workpiece fixed to a small hole electric discharge machine drill, the method comprising:

a first step of registering positional coordinates of a hole to be processed on a surface of the workpiece, a specified processing depth and tolerance of the specified processing depth with a process program;

a second step of providing a check point for checking an origin of initiation of drilling in a position on a surface of the workpiece and setting the origin of initiation of drilling by contacting a tip of a bar electrode with the check point;

a third step of moving the bar electrode to a position above a processing position of the hole to be processed and drilling until reaching the specified processing depth;

a fourth step of moving the tip of the bar electrode to a position above the check point on the surface of the workpiece after completing drilling in the third step;

a fifth step of moving the tip of the bar electrode traveled to the position above the check point downward until the tip of the bar electrode contacts the surface of the workpiece and finding a coordinate in a normal direction with respect to a plane of the workpiece when the tip of the bar electrode contacts the surface of the workpiece; and

a sixth step of judging a condition as to whether the coordinate found in the fifth step satisfies a value of the coordinate found in the fifth step \leq the tolerance,

wherein processing of the hole to be processed in the positional coordinates is completed if the condition is satisfied, and

if the condition is unsatisfied in the sixth step, the steps from the second step to the sixth step are iterated until the condition is satisfied.

2. A small hole electric discharge machine drill comprising:

depth-specific processing means for performing depth-specific processing by inputting at least a specified processing depth and tolerance of the specified processing depth,

wherein the depth-specific processing means further includes:

origin setting means for setting an origin of initiation of drilling;

process error detecting means for detecting an error of the specified processing depth; and

process error judging means for judging as to whether the tolerance of the specified processing depth and the process error detected by the process error detecting means satisfy a formula as defined by $|the\ process\ error| \leq the\ tolerance$.

3. A small hole electric discharge machine drill comprising:

a turntable having rotation axes of a first axis, of which a center of rotation is defined as a shaft center parallel to a processing axis, and a second axis, of which a center of rotation is defined as a shaft center orthogonal to the first axis, wherein the turntable is provided inside a work tank for filling a working fluid therein.

4. The small hole electric discharge machine drill according to claim 3,

wherein the turntable is disposed rotatably on one end inside the work tank of a second axis rotating shaft which extends from an outside of the work tank to an inside thereof,

the second axis rotating shaft is provided with a blind hole which has an opening outside the work tank and extends to an end portion inside the work tank,

a first axis drive motor is provided outside the work tank via the blind hole for rotating the turntable, and

a second axis drive motor is provided outside the work tank for driving the second axis rotating shaft.

5. The small hole electric discharge machine drill according to claim 4, further comprising:

an air chamber to shut out outside air from the blind hole of the second axis rotating shaft, wherein the first axis drive motor and the second axis drive motor are disposed inside the air chamber, and
air at about 1.1 atm. is always supplied to the air chamber from a pneumatic source.

5

6. The small hole electric discharge machine drill according to claim 3, further comprising:

10

Fluid level controller for controlling a fluid level of the working fluid inside the work tank in a level slightly higher than a surface of a workpiece.

15

7. The small hole electric discharge machine drill according to claim 6,
wherein the Fluid level controller comprises:

a notch provided on a sidewall of the work tank from an upper portion thereof downward;
a gate which ascends and descends along the notch ;
a nut member fitted to the gate; and
a driving portion which rotates the nut member,
and
the excess working fluid is allowed to overflow from the notch by moving the gate up and down by the driving portion.

(54) **Small hole electric discharge machine drill provided with depth-specific processing means and method of depth-specific processing with small hole electric discharge machine drill**

(57) Disclosed is a method of depth-specific processing with a small hole electric discharge machine drill. Firstly, a specified processing depth A and tolerance a are registered with a program. Secondary, an origin of initiation of drilling is set on a surface of a workpiece by contacting a tip of an electrode D with the surface of the workpiece at a check point. Thirdly, the electrode is moved to a processing position to process until the specified processing depth. Fourthly, the electrode is moved to a position above the check point. Fifthly, the electrode is moved downward until the electrode contacts the surface of the workpiece, a Z-axis coordinate upon contact is defined as C. And finally, a condition judgment is made concerning C which is found in the fifth step, as to whether or not $|C| \leq \alpha$ is satisfied. If the condition is satisfied, then processing is completed.

FIG.1

European Patent
Office

Application Number
EP 02 00 8030

CLAIMS INCURRING FEES

The present European patent application comprised at the time of filing more than ten claims.

- ☐ Only part of the claims have been paid within the prescribed time limit. The present European search report has been drawn up for the first ten claims and for those claims for which claims fees have been paid, namely claim(s):
- ☐ No claims fees have been paid within the prescribed time limit. The present European search report has been drawn up for the first ten claims.

LACK OF UNITY OF INVENTION

The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

see sheet B

- ☒ All further search fees have been paid within the fixed time limit. The present European search report has been drawn up for all claims.
- ☐ As all searchable claims could be searched without effort justifying an additional fee, the Search Division did not invite payment of any additional fee.
- ☐ Only part of the further search fees have been paid within the fixed time limit. The present European search report has been drawn up for those parts of the European patent application which relate to the inventions in respect of which search fees have been paid, namely claims:
- ☐ None of the further search fees have been paid within the fixed time limit. The present European search report has been drawn up for those parts of the European patent application which relate to the invention first mentioned in the claims, namely claims:

Office

LACK OF UNITY OF INVENTION
SHEET B

Application Number
EP 02 00 8030

The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

1. claims: 1,2

a method of depth-specific processing of a workpiece and a small hole electric discharge machining drill comprising depth-specific processing means.

2. claim: 3+4 and 3+4+5

A small hole electric discharge machine drill comprising a turntable having rotation axes of a first axis, and a second axis and provided inside a work tank as is known from JP58010427 and FR2473931 and having the additional feature of having a first and a second axis drive motor

3. claim: 3+6 and 3+6+7

A small hole electric discharge machine drill comprising a turntable having rotation axes of a first axis, and a second axis and provided inside a work tank as is known from JP58010427 and FR2473931 and having the additional feature of a fluid level controller.

**ANNEX TO THE EUROPEAN SEARCH REPORT
ON EUROPEAN PATENT APPLICATION NO.**

EP 02 00 8030

This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report. The members are as contained in the European Patent Office EDP file on
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
